## Report

## Data set: 721 Weight Training Workouts

-URL: <https://www.kaggle.com/datasets/joep89/weightlifting> (<https://www.kaggle.com/datasets/joep89/weightlifting>) (Kaggle) This data set provides the individual's weightlift routine with the types of exercises, the weight he lifted, the number of sets and reps he did, and the date of each workout for him. I am interested in working out, and I can consider myself a gym lover. As a gym lover, I am eager to have better performance in weightlifting and bodybuilding, and I believe it would be helpful for me to have better performance analyzing this data set. As analyzing the data set, I hope to identify the patterns in the training strategies, tips to get stronger, and some insights he improved his performance. I hope I can also analyze the mechanism he improved his performance and apply it to myself.

## What Interesting thing I discovered

I discovered that the Hammer high row has the highest betweenness centrality of 213.61903558034524. It implies that hammer high row might be the most important and influential exercises in terms of their association with improved performance in that high betweenness centrality suggests the node with the high betweenness centrality have considerable influence over the information passing between other nodes. However, still some other well known important exercises like squat and dead lift shows high centrality scores of 105.79072168385757 and 113.78611917095613, so I can assume not only hammer high row, but also those two exercises are influential over other workout patterns associated to improved performance.

## What algorithms I implemented/ what the project does/ how to run it

I implemented betweenness centrality measure algorithm based on Dijkstra's shortest path algorithm in my project. To compute the betweenness centrality, I needed to perform Dijkstra's algorithm to find shortest path between the vertices and then compute the betweenness centrality because my graph is weighted. To calculate betweenness centrality, I take every pair of the network and count how many times a node can interrupt the shortest paths between the two nodes of the pair;  $(n-1)(n-2)/2$ . With the shortest paths calculated by Dijkstra's algorithm, I computed betweenness centrality of each nodes from the start node. Therefore, for my dataset, the project reads a data set from csv file and constructs directed weighted graph using petgraph, and finds a node with the high betweenness centrality measure algorithm that can be assumed it has relatively crucial impact over other exercises in terms of their connections to other exercises using Dijkstra algorithm based betweenness centrality algorithm.

And the complexitiy of my Dijkstra's algorithm would be  $O((E+V)\log V)$  where E is the number of edges and V is the number of vertices vistied, so my graph has 9302 edges and 9303 nodes,  $O(18605)\log 9303$ , and for the betweennes algorithm, it would have  $O(V(E+V)\log V)$ , so  $O(9303(18605)\log 9303)$ . And, overall, it would be  $O(V(E+V)\log V)$ , so  $O(9303(18605)\log 9303)$ .

## Conclusions/Findings

**Do the highest centrality vertices match your intuition? What happens when you look at some meaningful subgraphs. Is this the case for them? What the output looks like?**

The highest centrality vertices does not really match my intuition. I expected deadlift or barbel squat to be the highest centrality vertices because it is well known that squat and deadlift helps to improve the overall performance of the weightlifting, but the Hammer high row was the vertice with the highest centrality vertices. However, When I look at some meaningful subgraphs and other centralities, deadlift, squat, bench press and some other exercises that I expected to have the highest centrallites are also located at top 10 highest centralities. It means they also might be influential to other exercises and a key exercise to help to improve the overall performance. So, I can say the centrality algorithm not perfectly, but certainly worked on my project and intuition.

## Outcome

When I output shortest path from Dijkstra algorithm and centrality scores, there are some None and 0 values I think it is because some of my nodes names in the data set has the redundant name with the same weight since the kind of exercises are limited and the amount of weight lifted can not improve in short term.

## Graph Nodes/Edges

Graph represented without weight in the form of integer with # of nodes and edges

```

Graph ( Ty: "Directed", node_count: 9303, edge_count: 9302, edges: (0, 1), (1, 2), (2, 1), (1, 4), (4, 5), (5, 6), (6, 7), (7, 8), (8, 9), (9, 10), (10, 11), (11, 12), (12, 13), (13, 10), (10, 15), (15, 1
